Anti-K poisoning  
Mechanism

## ABSTRACT

The CeO<sub>2</sub>-WO<sub>3</sub> catalyst used for NO<sub>x</sub> abatement in biomass boiler combustion was prone to severe deactivation due to the high alkali metal content in exhaust gas. Enhancing the alkali resistance of the CeO<sub>2</sub>-WO<sub>3</sub> catalyst was crucial for its practical application. In this study, the CeO<sub>2</sub>-WO<sub>3</sub>/MCM-22 catalysts were synthesized via a simple impregnation method, resulting in a minimal reduction in catalyst activity after 1 wt% K<sub>2</sub>O poisoning. The anti-K poisoning mechanism of CeO<sub>2</sub>-WO<sub>3</sub>/MCM-22 catalyst was studied. The results demonstrated that the acid sites of lamellar MWW-Type molecular sieve MCM-22 (Mobil composition of matter-22) acted as sacrificial sites, effectively trapping the alkali poisoning and protecting the CeO<sub>2</sub>-WO<sub>3</sub> active component. Compared with CeO<sub>2</sub>-WO<sub>3</sub> catalyst, the Brønsted acid sites on the cerium tungstate occupied by foreign K, were liberated as K element preferentially bound to the molecular sieve MCM-22.

## 1. Introduction

The emission of nitrogen oxides (NO<sub>x</sub>) from human production and transportation processes gives rise to detrimental environmental impacts, including acid rain, photochemical smog, and haze that degrades the ecological environment [1–3]. Importantly, NH<sub>3</sub>-SCR technology can convert NO<sub>x</sub> into N<sub>2</sub> and H<sub>2</sub>O, the core of technology is development of efficient catalyst [4]. The commercial V<sub>2</sub>O<sub>5</sub>-WO<sub>3</sub>/TiO<sub>2</sub> catalyst possesses satisfactory NO<sub>x</sub> removal performance and splendid resistance to water (H<sub>2</sub>O) and Sulphur dioxide (SO<sub>2</sub>) at medium and high temperatures (300–400 °C). However, the vanadium species of V<sub>2</sub>O<sub>5</sub>-WO<sub>3</sub>/TiO<sub>2</sub> catalyst are toxic and the catalyst is prone to cumulative deactivation due to alkali metals (K, Na) presented in exhaust gas. Commercial catalysts applied in power plants and industrial boilers require replacement or regeneration operations every 2–5 years, which significantly increases operational costs [5–7]. Additionally, owing to the promotion of sustainable development concepts and the improvement of environmental quality requirements, biomass fuels will substitute conventional fossil fuels, leading to an increase in alkali metal content in exhaust gas

and expedited deactivation of catalysts [8,9]. Hence, there is a pressing need to design an environmentally friendly and robust deNO<sub>x</sub> catalyst with remarkable alkali metal tolerance.

Currently, researchers have designed catalysts with high alkali tolerance by doping with elements (metal or nonmetal), separating catalytic active sites and toxic capture sites, and using appropriate carriers. Zhang et al. [10] investigated the B-doped CeO<sub>2</sub>/TiO<sub>2</sub> catalyst. The results indicated that the Ce–O–B sites formed by B doping could preferentially bind with K, which effectively alleviates catalyst poisoning by K. Feng et al. [9] prepared Fe<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>/TiO<sub>2</sub> catalyst with remarkable tolerance to alkali metals, which was attributable to the interaction between the active sites and poisoning sites. Ji et al. [11] synthesized a CeMn–ZSM-5 hybrid catalyst, which expressed ~10% reduction in activity after 2 wt% K<sub>2</sub>O poisoning. The results revealed that this was primarily due to the preferential combination of K poisons with the Lewis (L) acid sites of molecular sieve ZSM-5. Chen et al. [12] synthesized sulfated CeO<sub>2</sub> catalysts through a simple impregnation method. The surface Ce<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub> species can preferentially combine with K, while the active sites were reserved, endowing the sulfated CeO<sub>2</sub>

catalyst with prominent tolerance to K. Zhou et al. [13] employed TiO<sub>2</sub> pillared montmorillonite with self-created targeted anti-poisoning sites as support, which effectively prevented active CeO<sub>2</sub> component from being poisoned. In summary, introducing sacrificial sites to anchor alkali poisons is a feasible method to enhance the alkali resistance of the catalyst, thereby preserving the active sites.

CeO<sub>2</sub> possesses a unique versatile structural arrangement and electronic features, which endow it with excellent redox properties and remarkable oxygen storage capacity (OSC), making it potentially efficient substitute for vanadium-based catalysts [14,15]. Nonetheless, due to the insufficient acidity of single CeO<sub>2</sub> catalyst, its catalytic performance is not satisfactory. Therefore, a second additive is usually added to enhance the catalytic performance of the CeO<sub>2</sub> catalyst. Shan et al. [16] prepared a new CeO<sub>2</sub>-WO<sub>3</sub> catalyst with outstanding activity at medium and high temperatures. It was observed that tungsten oxide provided acidity and there was a synergistic effect between cerium and tungsten species. Peng et al. [17] investigated that alkali metals deactivate CeO<sub>2</sub>-WO<sub>3</sub> catalyst. The results showed that the catalyst deactivation was attributable to the reduction of reducibility and the quantity of B acid sites. Subsequently, Peng et al. [18] studied the active site of CeO<sub>2</sub>-WO<sub>3</sub> catalyst and both acid and redox cycle exist on the CeO<sub>2</sub>-WO<sub>3</sub> catalyst. However, severe deactivation of the CeO<sub>2</sub>-WO<sub>3</sub> catalyst due to the alkali metals (K, Na) presented in the exhaust emissions is currently a major challenge for practical applications. Mobil composition of matter-22 (MCM-22) is a layered MWW-Type molecular sieve with two sets of independent pore structures. One is a two-dimensional sinusoidal channel with an elliptical ring cross section (4.1 × 5.1 Å), and the other is a cylindrical 12-member-ring super-cage (7.1 × 7.1 × 18.2 Å) [19,20]. MCM-22 possesses characteristics of a large specific surface area (usually 400–500 m<sup>2</sup>·g<sup>-1</sup>), excellent thermal/hydrothermal stability, strong adsorption capacity and tunable acidity over a wide range. These properties endow MCM-22 with a significant ability to anchor foreign alkali poisons and protect the active component.

In this study, diverse CeO<sub>2</sub>-WO<sub>3</sub>/MCM-22 catalysts were synthesized using a simple impregnation method. The catalysts exhibited minimal reduction in activity after 1 wt% K<sub>2</sub>O poisoning and maintained good activity after 2 wt% K<sub>2</sub>O poisoning. The properties and reaction mechanism of the CeO<sub>2</sub>-WO<sub>3</sub> and CeO<sub>2</sub>-WO<sub>3</sub>/MCM-22 catalysts were systematically studied through experiments and DFT calculations. Characterization results showed that the acid sites of lamellar MWW-type molecular sieve MCM-22 acted as sacrificial sites to trap K poisons, protecting the active CeO<sub>2</sub>-WO<sub>3</sub> component. Meanwhile, the DFT calculations further confirmed that K was trapped in the molecular sieve MCM-22, which corresponded to experimental results. Moreover, through recombination with MCM-22, the B acid sites on the Ce-W occupied by K were liberated. This enabled the maintenance of high-efficiency acid site cycling (NH<sub>3</sub> adsorption) and the restoration of the catalytic reaction path. The research conducted in this study establishes a theoretical foundation for the development of an environmentally friendly and robust *de*NO<sub>x</sub> NH<sub>3</sub>-SCR catalyst with exceptional resistance to K.

## 2. Materials and methods

### 2.1. Catalyst synthesis

The *x*%CeO<sub>2</sub>-WO<sub>3</sub>/MCM-22 (*x* = 10, 20, and 30) catalysts were synthesized via the impregnation method. For comparison, the CeO<sub>2</sub>-WO<sub>3</sub> was synthesized via the co-precipitation method. K-poisoned CeO<sub>2</sub>-WO<sub>3</sub>/MCM-22-*y*%K or CeO<sub>2</sub>-WO<sub>3</sub>-*y*%K (*y* = 1, 1.5, and 2) catalysts were simulated via the impregnation method. The detailed preparation process for these catalysts is shown in [Supplementary material \(SM\)](#).

### 2.2. Catalytic performance evaluations

The *de*NO<sub>x</sub> performance of the obtained catalysts was evaluated in a self-assembled fixed-bed quartz reactor with continuous flow. The testing details of catalytic activity, kinetics experiments, catalyst characterization and DFT calculation are shown in the [SM](#).

## 3. Results and discussion

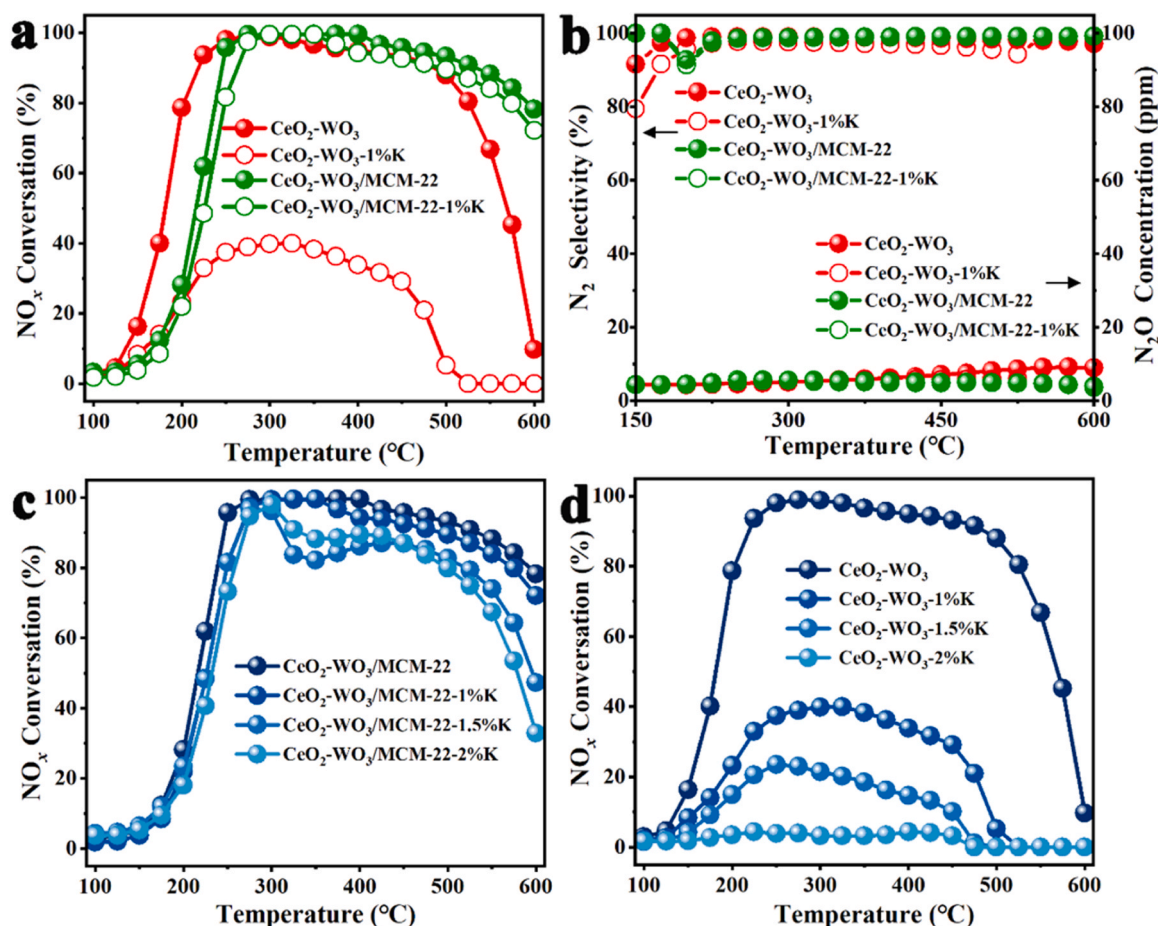

### 3.1. *de*NO<sub>x</sub> performance and K resistance analysis

According to the [Fig. S1](#), the 20%CeO<sub>2</sub>-WO<sub>3</sub>/MCM-22 (CeO<sub>2</sub>-WO<sub>3</sub>/MCM-22 for short) exhibited the optimal catalytic activity and was selected for all subsequent analyses. [Fig. 1](#) illustrates the NO<sub>x</sub> conversion, N<sub>2</sub> selectivity and N<sub>2</sub>O concentration of CeO<sub>2</sub>-WO<sub>3</sub>, CeO<sub>2</sub>-WO<sub>3</sub>/MCM-22, CeO<sub>2</sub>-WO<sub>3</sub>-*y*%K and CeO<sub>2</sub>-WO<sub>3</sub>/MCM-22-*y*%K catalysts across the temperature range of 100–600 °C. CeO<sub>2</sub>-WO<sub>3</sub>-1%K catalyst significantly loss of activity with maximum 40% NO<sub>x</sub> conversion at 325 °C. For comparison, CeO<sub>2</sub>-WO<sub>3</sub>/MCM-22-1%K catalyst reached 100% NO<sub>x</sub> conversion at 325 °C and maintained good catalytic activity within the temperature range of 275–550 °C ([Fig. 1a](#)). Meanwhile, The CeO<sub>2</sub>-WO<sub>3</sub> and CeO<sub>2</sub>-WO<sub>3</sub>/MCM-22 catalyst exhibited high N<sub>2</sub> selectivity (> 90%) and low N<sub>2</sub>O concentration (< 10 ppm) between 200–600 °C ([Fig. 1b](#)). Moreover, with an increase of K loading from 1–2 wt%, no noticeable decrease in activity was observed on CeO<sub>2</sub>-WO<sub>3</sub>/MCM-22 and the catalytic activity reached over 95% NO<sub>x</sub> conversion at 300 °C, showcasing the remarkable K resistance of the catalyst ([Fig. 1c](#)). In contrast, CeO<sub>2</sub>-WO<sub>3</sub> catalyst exhibited low K resistance, with almost complete deactivation observed when the K<sub>2</sub>O loading reached 2 wt% ([Fig. 1d](#)). In addition, the intrinsic activation energy (*E<sub>a</sub>*) of the CeO<sub>2</sub>-WO<sub>3</sub>/MCM-22 and CeO<sub>2</sub>-WO<sub>3</sub>/MCM-22-1%K catalysts were also evaluated. The NO<sub>x</sub> conversion remained below < 15% to eliminate the effects of internal and external diffusion ([Fig. S3](#)). The *E<sub>a</sub>* of the fresh CeO<sub>2</sub>-WO<sub>3</sub>/MCM-22 catalyst was 78 kJ·mol<sup>-1</sup>. After K poisoning, the *E<sub>a</sub>* of CeO<sub>2</sub>-WO<sub>3</sub>/MCM-22-1%K catalyst slightly increased to 80 kJ·mol<sup>-1</sup>, which was consistent with the activity tests of CeO<sub>2</sub>-WO<sub>3</sub>/MCM-22 and CeO<sub>2</sub>-WO<sub>3</sub>/MCM-22-1%K. To explore the reason for the high resistance of catalyst to K poisoning, CeO<sub>2</sub>-WO<sub>3</sub>/MCM-22-1%K (CeO<sub>2</sub>-WO<sub>3</sub>/MCM-22-1%K for short) with exceptional resistance to K was selected for all subsequent analyses.

### 3.2. Chemical states analysis

Raman spectroscopy analysis was performed on CeO<sub>2</sub>-WO<sub>3</sub>, CeO<sub>2</sub>-WO<sub>3</sub>/MCM-22, CeO<sub>2</sub>-WO<sub>3</sub>-K and CeO<sub>2</sub>-WO<sub>3</sub>/MCM-22-K, to further characterize the presence of components on the surface of the catalyst ([Fig. S9](#)). A peak at 464 cm<sup>-1</sup>, corresponding to the F<sub>2g</sub> pattern of the symmetrical vibration of oxygen atoms around the Ce in CeO<sub>2</sub> of cubic fluorite was observed. Additionally, a peak at 969 cm<sup>-1</sup>, attributable to the stretching vibration pattern of heteropolymorphism species WO<sub>2(t)</sub> was observed [18,21,22]. The peak intensity of CeO<sub>2</sub>-WO<sub>3</sub>-K and CeO<sub>2</sub>-WO<sub>3</sub>/MCM-22-K at 460 cm<sup>-1</sup> was increased, indicating Ce aggregation caused by K. The Raman spectroscopy result was consistent with the XRD analysis.

The reducibility property of a catalyst is significant for its deactivation, with Alkali metals like K usually reducing this property [23–25]. Therefore, it was important to investigate changes in the reducibility performance over CeO<sub>2</sub>-WO<sub>3</sub>, CeO<sub>2</sub>-WO<sub>3</sub>/MCM-22, CeO<sub>2</sub>-WO<sub>3</sub>-K and CeO<sub>2</sub>-WO<sub>3</sub>/MCM-22-K catalysts. The above catalysts were characterized by H<sub>2</sub>-TPR ([Fig. 2a](#)). For CeO<sub>2</sub>-WO<sub>3</sub> catalyst, one peak at 559 °C attributed to Ce<sup>4+</sup> and Ce<sup>4+</sup>-O-Ce<sup>3+</sup> species on the surface was observed. The CeO<sub>2</sub>-WO<sub>3</sub>-K catalyst exhibited two reduction peaks at 598 and 630 °C, which attributable to the reduction of Ce<sup>4+</sup> and Ce<sup>4+</sup>-O-Ce<sup>3+</sup> species on the surface. The CeO<sub>2</sub>-WO<sub>3</sub>/MCM-22 exhibited four reduction peaks, with the peaks at 551 and 732 °C attributable to the reduction of surface oxygen and Ce<sup>4+</sup> species in the bulk phase, respectively,

**Fig. 1.** (a)  $\text{NO}_x$  conversion, (b)  $\text{N}_2$  selectivity and  $\text{N}_2\text{O}$  concentration during the SCR reaction over  $\text{CeO}_2\text{-WO}_3$ ,  $\text{CeO}_2\text{-WO}_3/\text{MCM-22}$ ,  $\text{CeO}_2\text{-WO}_3\text{-1\%K}$  and  $\text{CeO}_2\text{-WO}_3/\text{MCM-22-1\%K}$  catalysts; (c)  $\text{NO}_x$  conversion during the SCR reaction over  $\text{CeO}_2\text{-WO}_3/\text{MCM-22-}\gamma\text{\%K}$  and (d)  $\text{CeO}_2\text{-WO}_3\text{-}\gamma\text{\%K}$  catalysts. Reaction conditions:  $[\text{NO}] = [\text{NH}_3] = 500 \text{ ppm}$ ,  $[\text{O}_2] = [\text{H}_2\text{O}] = 5 \text{ vol\%}$ ,  $\text{N}_2$  balanced,  $\text{WHSV} = 60,000 \text{ mL}\cdot\text{g}_{\text{cat}}^{-1}\cdot\text{h}^{-1}$ .

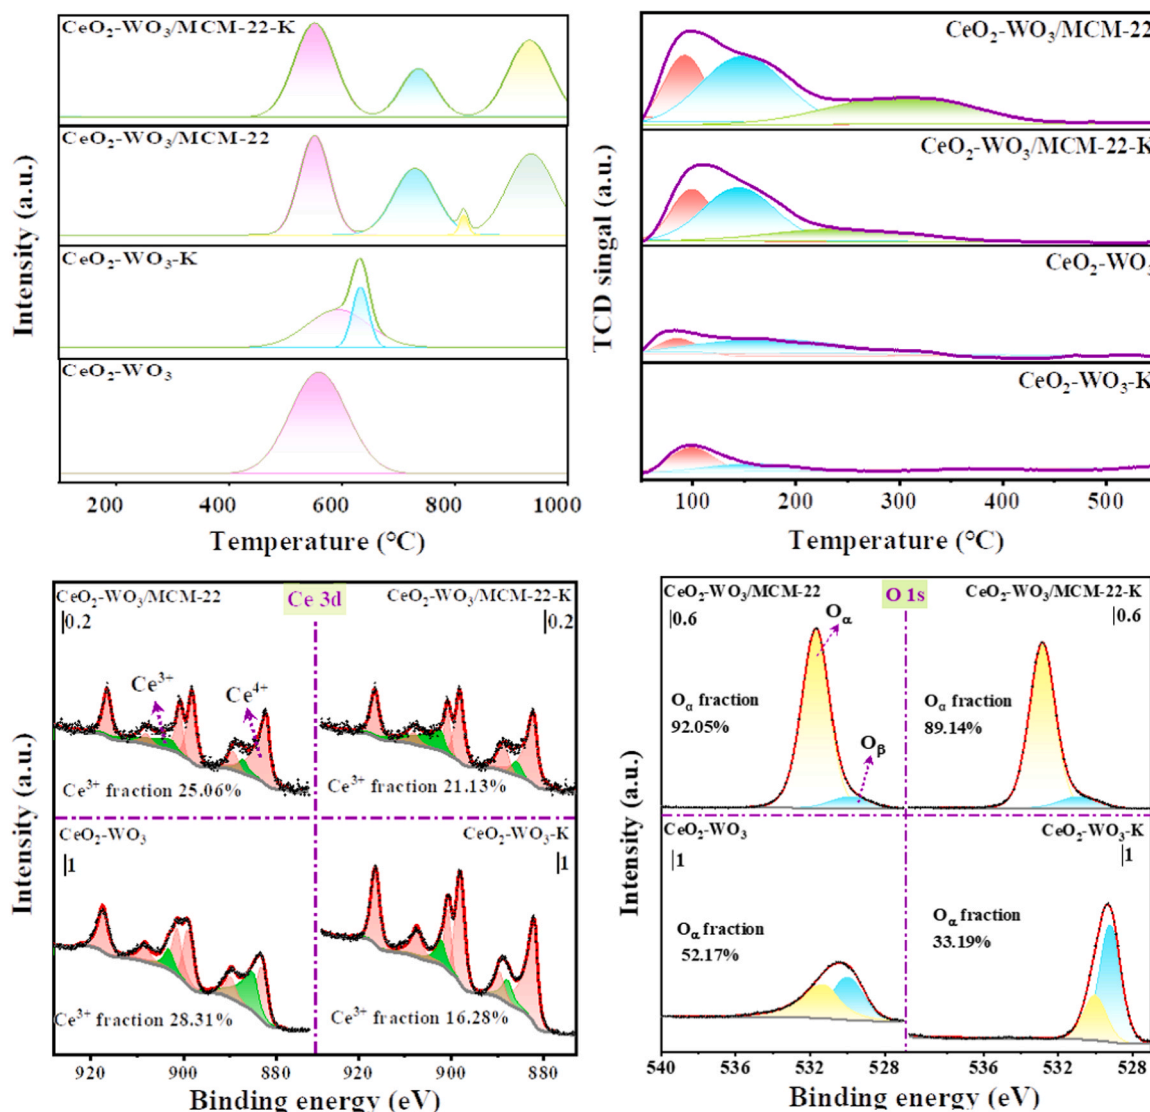

while the peaks at 814 and 938  $^\circ\text{C}$  attributable to the reduction of  $\text{W}^{6+} \rightarrow \text{W}^0$ . The  $\text{CeO}_2\text{-WO}_3/\text{MCM-22-K}$  exhibited three reduction peaks, with the peaks at 558 and 736  $^\circ\text{C}$  attributable to the reduction of surface oxygen and  $\text{Ce}^{4+}$  species in the bulk phase, while the peak at 938  $^\circ\text{C}$  attributable to the reduction of  $\text{W}^{6+} \rightarrow \text{W}^0$  [26,27]. The reduction temperature of  $\text{CeO}_2\text{-WO}_3\text{-K}$  catalyst increased to a higher temperature by 39  $^\circ\text{C}$  from 559 to 598  $^\circ\text{C}$ , while the reduction temperature of the  $\text{CeO}_2\text{-WO}_3/\text{MCM-22-K}$  shifted slightly to high temperature, with a temperature increase of  $< 10$   $^\circ\text{C}$ . In addition, compared with  $\text{CeO}_2\text{-WO}_3$ , the reduction temperature of surface oxygen decreased to a lower temperature, indicating  $\text{Ce}^{4+}$  was more easily reduced with the MCM-22 and thus improved the  $\text{NO}_x$  reduction activity. It was well recognized that the acid sites and redox sites are crucial for rendering a SCR catalyst with high-performance, which influence the adsorption/activation of  $\text{NH}_3$  and  $\text{NO}_x$  [28]. These results indicated that the reducibility of the  $\text{CeO}_2\text{-WO}_3/\text{MCM-22}$  catalyst expressed no obvious variation, which corresponded to the activity test results". Thus, the maintained reducing property of the  $\text{CeO}_2\text{-WO}_3/\text{MCM-22}$  catalyst was an important factor that contributed to the excellent K resistance.

Acidity is a crucial parameter for catalytic performance, as  $\text{NH}_3$  species were absorbed on acid sites, which was a prerequisite for the  $\text{NH}_3\text{-SCR}$  reaction [29]. Foreign K poisons typically occupied the acid sites of the catalyst, inhibiting the  $\text{NH}_3$  adsorption, hindering the  $\text{deNO}_x$  reaction, and significantly reducing the catalytic activity [30]. To investigate the impact of K poisons on catalyst acidity,  $\text{NH}_3\text{-TPD}$  tests were conducted on  $\text{CeO}_2\text{-WO}_3$ ,  $\text{CeO}_2\text{-WO}_3/\text{MCM-22}$ ,  $\text{CeO}_2\text{-WO}_3\text{-K}$  and  $\text{CeO}_2\text{-WO}_3/\text{MCM-22-K}$  (Fig. 2b). The  $\text{CeO}_2\text{-WO}_3/\text{MCM-22}$  exhibited three desorption peaks corresponding to weak  $\text{NH}_3$  adsorption  $< 300$   $^\circ\text{C}$

and strong  $\text{NH}_3$  adsorption  $> 300$   $^\circ\text{C}$  [31]. The strong acid amount of  $\text{CeO}_2\text{-WO}_3/\text{MCM-22-K}$  was reduced, and the overall acid content remained high (Fig. S10). The  $\text{CeO}_2\text{-WO}_3$  exhibited two desorption peaks corresponding to weak  $\text{NH}_3$  adsorption, and the acid amount decreased after K poisoning. In addition, quantitative results further revealed detailed information on the amount of  $\text{NH}_3$  desorption (Table S3). The total acid content of the  $\text{CeO}_2\text{-WO}_3/\text{MCM-22}$  was  $8.4 \text{ mmol}\cdot\text{g}^{-1}$ , which was 4.4 times higher than that of  $\text{CeO}_2\text{-WO}_3$  ( $1.9 \text{ mmol}\cdot\text{g}^{-1}$ ), indicating that the introduction of MCM-22 increased both acidity and acid sites [32]. This increase was attributable to the presence of L acid sites on the tetrahedral Al site of the molecular sieve and B acid sites in the molecular sieve skeleton. The total acid content of  $\text{CeO}_2\text{-WO}_3/\text{MCM-22-K}$  reached  $5.5 \text{ mmol}\cdot\text{g}^{-1}$ , which was  $\sim 2.9$  times that of fresh  $\text{CeO}_2\text{-WO}_3$  ( $1.9 \text{ mmol}\cdot\text{g}^{-1}$ ). These results indicating that  $\text{CeO}_2\text{-WO}_3/\text{MCM-22}$  exhibited high acidity, and the  $\text{CeO}_2\text{-WO}_3/\text{MCM-22-K}$  catalyst also exhibited a higher acid content than the  $\text{CeO}_2\text{-WO}_3$  catalyst.

The oxidation states and concentrations of surface metal elements were analyzed, and XPS tests were conducted on  $\text{CeO}_2\text{-WO}_3$ ,  $\text{CeO}_2\text{-WO}_3/\text{MCM-22}$ ,  $\text{CeO}_2\text{-WO}_3\text{-K}$  and  $\text{CeO}_2\text{-WO}_3/\text{MCM-22-K}$ . The XPS spectra of Ce, O and W were shown in Fig. 2c, d and Fig. S11, and the corresponding concentration of elements were summarized in Table S3. The catalysts peaks were calibrated to 284.8 eV on the C 1 s peak. The XPS spectra of Ce 3d from various catalysts were observed, and no significant binding energy (BE) shift was observed in Ce between  $\text{CeO}_2\text{-WO}_3/\text{MCM-22}$  and  $\text{CeO}_2\text{-WO}_3/\text{MCM-22-K}$  (Fig. 2c). Meanwhile, no apparent change was observed in  $\text{Ce}^{3+}/\text{Ce}$  ratio (25.1% vs. 21.1%). In contrast, the  $\text{Ce}^{3+}/\text{Ce}$  ratio exhibited a noticeable loss (28.3% vs.

**Fig. 2.** (a)  $\text{H}_2$ -TPR and (b)  $\text{NH}_3$ -TPD profiles for  $\text{CeO}_2\text{-WO}_3$ ,  $\text{CeO}_2\text{-WO}_3/\text{MCM-22}$ ,  $\text{CeO}_2\text{-WO}_3\text{-K}$  and  $\text{CeO}_2\text{-WO}_3/\text{MCM-22-K}$ ; (c) XPS of Ce 3d and (d) O 1s for  $\text{CeO}_2\text{-WO}_3$ ,  $\text{CeO}_2\text{-WO}_3/\text{MCM-22}$ ,  $\text{CeO}_2\text{-WO}_3\text{-K}$  and  $\text{CeO}_2\text{-WO}_3/\text{MCM-22-K}$ .

16.3%) on  $\text{CeO}_2\text{-WO}_3$  and  $\text{CeO}_2\text{-WO}_3\text{-K}$ . It has been reported that  $\text{Ce}^{3+}$  can react with  $\text{O}_2$  to form  $\text{O-Ce}^{4+}$  species, which can activate the  $\text{NH}_3$  adsorbed on the  $\text{W=O}$  species of cerium tungstate. According to previously published literature [33], the increased  $\text{O-Ce}^{4+}$  formation promoted the redox cycle on the  $\text{CeO}_2\text{-WO}_3/\text{MCM-22}$  catalyst". Fig. 2d depicts the XPS spectra of O 1s from the catalysts, and the fitting peaks of BE at 531.0–533.0 eV and 529.0–531.0 eV were attributable to the chemisorbed oxygen (denoted  $\text{O}_\alpha$ ) and lattice oxygen (denoted  $\text{O}_\beta$ ), respectively [34,35]. In the quantitative calculation of the  $\text{O}_\alpha/\text{O}$  ratio from various catalysts, a negligible reduction in the  $\text{O}_\alpha/\text{O}$  ratio was observed on  $\text{CeO}_2\text{-WO}_3/\text{MCM-22}$  and  $\text{CeO}_2\text{-WO}_3/\text{MCM-22-K}$  (92.1% vs. 89.1%). Compared with  $\text{CeO}_2\text{-WO}_3$ ,  $\text{CeO}_2\text{-WO}_3/\text{MCM-22}$  exhibiting higher  $\text{O}_\alpha/\text{O}$  ratio, it can be reasonably speculated that the hydroxyl groups on the molecular sieve MCM-22 adsorbed abundant oxygen. However, the  $\text{O}_\alpha/\text{O}$  ratio exhibited a significant decrease (52.2% vs. 33.2%) on  $\text{CeO}_2\text{-WO}_3$  and  $\text{CeO}_2\text{-WO}_3\text{-K}$ . Generally,  $\text{O}_\alpha$  exhibited higher reactivity than  $\text{O}_\beta$  owing to its high reactivity mobility, which was beneficial to the SCR reaction [36,37]. The XPS spectra of W 4f from the catalysts were observed (Fig. S11). Two distinct peaks in the BE of 32.0–48.0 eV was observed, which were consistent with the W 4f<sub>7/2</sub> and W 4f<sub>5/2</sub> peaks of pure  $\text{WO}_3$ , indicating that W element existed in the form of  $\text{W}^{6+}$  in the catalyst. Meanwhile, the  $\text{CeO}_2\text{-WO}_3\text{-K}$  exhibited a

$\text{WO}_3$  loss feature peak at 42.0 eV (Fig. S11). According to the above results, compared with  $\text{CeO}_2\text{-WO}_3$ , the ratio of  $\text{Ce}^{3+}$ , and  $\text{O}_\alpha$  on  $\text{CeO}_2\text{-WO}_3/\text{MCM-22-K}$  exhibited no apparent variation. Combining the experimental results of  $\text{H}_2$ -TPR and  $\text{NH}_3$ -TPD, it is inferred that acid sites introduced by MCM-22 tend to preferentially combine with foreign poisons K as sacrificial sites, thus effectively alleviating K-induced deactivation of  $\text{CeO}_2\text{-WO}_3$ .

### 3.3. Adsorption performance of gas molecules on $\text{CeO}_2\text{-WO}_3/\text{MCM-22-K}$ catalyst

According to the  $\text{NH}_3$ -TPD results and  $\text{deNO}_x$  reaction performed, the K element was deposited at the acid site on the surface of MCM-22 in the  $\text{CeO}_2\text{-WO}_3/\text{MCM-22-K}$  catalyst. Thus, the K element simulated the poisoning process of  $\text{CeO}_2\text{-WO}_3/\text{MCM-22}$  catalysts. Fig. S12 exhibited the model of the optimized  $\text{CeO}_2\text{-WO}_3/\text{MCM-22-K}$  catalyst structure. It was observed that K was steadily adsorbed in molecular sieve MCM-22, which effectively protected the active  $\text{CeO}_2\text{-WO}_3$  component from deactivation by K poisoning. Further confirming our previous speculation, the introduced acid sites of the molecular sieve MCM-22 were used as sacrificial sites to trap foreign K poison, thus, the loss of activity was restored. To elucidate the adsorption performance and analyze

interatomic interactions on  $\text{CeO}_2\text{-WO}_3/\text{MCM-22-K}$ , the adsorption energy ( $E_{\text{ads}}$ ) and projected density of states (PDOS) of NO,  $\text{NO}_2$ ,  $\text{NH}_3$  and  $\text{O}_2$  gas molecules on  $\text{CeO}_2\text{-WO}_3/\text{MCM-22-K}$  surface were studied (Fig. 3). The calculated  $E_{\text{ads}}$  of all gas molecules on  $\text{CeO}_2\text{-WO}_3/\text{MCM-22-K}$  surface were  $< 0$ , indicating that the reactant gas molecules were easily adsorbed on  $\text{CeO}_2\text{-WO}_3/\text{MCM-22-K}$  surface, which was beneficial to  $\text{NH}_3\text{-SCR}$  reaction. The overlap of W 5d and N 2p orbitals in NO in a wide range was attributable to interorbital hybridization, indicating a strong interaction between NO and the catalyst, thus, a strong adsorption of NO was observed on the catalyst. Similarly, strong interactions between NO,  $\text{NO}_2$ ,  $\text{NH}_3$  and  $\text{O}_2$  gas molecules and  $\text{CeO}_2\text{-WO}_3/\text{MCM-22-K}$  catalyst were observed, indicating that the reactant gas molecules were strongly adsorbed on the  $\text{CeO}_2\text{-WO}_3/\text{MCM-22-K}$  catalyst surface. These results corresponded to the experimental results, confirming that the acid sites of MCM-22 molecular sieve acted as sacrificial sites and prevented the active component against K poisoning.

### 3.4. Reaction mechanism analysis

To elucidate reactive species and reaction mechanism, in situ diffuse reflectance infrared Fourier transform spectroscopy (DRIFTS) characterization was conducted on the catalysts. Initially, the catalysts were pretreated in  $\text{N}_2$  air flow ( $45 \text{ mL}\cdot\text{min}^{-1}$ ) at  $400^\circ\text{C}$  for 1 h to remove surface moisture and impurities. The catalysts were treated in  $\text{NH}_3$  air flow ( $5 \text{ mL}\cdot\text{min}^{-1}$ ) for 1 h, and the in situ DRIFTS of  $\text{NH}_3$  adsorption over  $\text{CeO}_2\text{-WO}_3$  and  $\text{CeO}_2\text{-WO}_3/\text{MCM-22}$  were observed (Fig. S14a,b). Several signal peaks ascribed to asymmetric bending vibration of ionic  $\text{NH}_4^+$  ( $1471 \text{ cm}^{-1}$ ), asymmetric and symmetric bending vibrations of coordinated  $\text{NH}_3$  ( $1600$  and  $1288 \text{ cm}^{-1}$ ) were detected on  $\text{CeO}_2\text{-WO}_3/\text{MCM-22}$  after the  $\text{NH}_3$  adsorption [38]. Meanwhile, several signals belonging to symmetric and asymmetric bending vibrations of ionic  $\text{NH}_4^+$  ( $1666$  and  $1421 \text{ cm}^{-1}$ ), asymmetric and symmetric bending vibrations of coordinated  $\text{NH}_3$  ( $1591$  and  $1180 \text{ cm}^{-1}$ ) were detected on  $\text{CeO}_2\text{-WO}_3$  after the adsorption of  $\text{NH}_3$  [39–41]. These results indicated

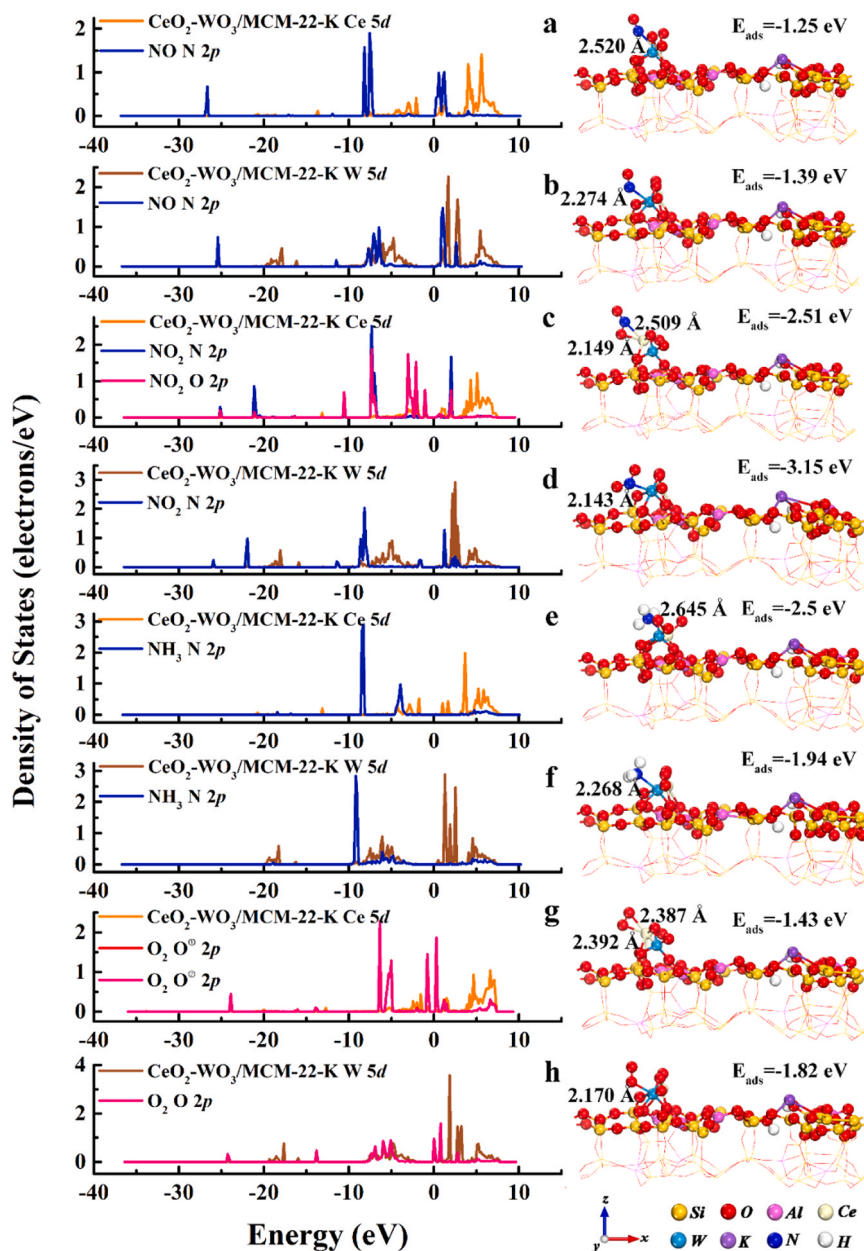

Fig. 3. (a–h) Adsorption configurations, adsorption energy ( $E_{\text{ads}}$ ) and Project density of states (PDOS) of NO,  $\text{NO}_2$ ,  $\text{NH}_3$  and  $\text{O}_2$  gas molecules on the  $\text{CeO}_2\text{-WO}_3/\text{MCM-22-K}$  catalyst surface, respectively.

that both  $\text{CeO}_2\text{-WO}_3$  and  $\text{CeO}_2\text{-WO}_3/\text{MCM-22}$  contained abundant acid sites, which were used for  $\text{NH}_3$  adsorption. Fig. S14c,d shows the in situ DRIFTS results of  $\text{NO}+\text{O}_2$  reaction with pre-adsorbed  $\text{NH}_3$  over  $\text{CeO}_2\text{-WO}_3$  and  $\text{CeO}_2\text{-WO}_3/\text{MCM-22}$  at  $200^\circ\text{C}$ . For  $\text{CeO}_2\text{-WO}_3/\text{MCM-22}$ , the peaks assigned to B ( $1471\text{ cm}^{-1}$ ) and L ( $1600$  and  $1288\text{ cm}^{-1}$ ) acid sites were detected. After passing  $\text{NO}+\text{O}_2$ , the B acid sites and L acid sites diminished within 40 min. Simultaneously, the bidentate nitrate species exhibited a signal peak ( $1579\text{ cm}^{-1}$ ).

Compared with  $\text{CeO}_2\text{-WO}_3$ , the peaks attributable to B ( $1666$  and  $1421\text{ cm}^{-1}$ ) and L ( $1591$  and  $1180\text{ cm}^{-1}$ ) acid sites were observed. After passing  $\text{NO}+\text{O}_2$ , the peak of ammonia species adsorbed on B acid sites and L acid sites disappeared within 30 min. Simultaneously, the adsorbed  $\text{NO}_2$  species exhibited the signal peak ( $1604\text{ cm}^{-1}$ ), indicating that the “Fast-SCR” reaction occurred on  $\text{CeO}_2\text{-WO}_3$ . The in situ DRIFTS results of  $\text{NH}_3$  reaction with pre-adsorbed  $\text{NO}+\text{O}_2$  over  $\text{CeO}_2\text{-WO}_3$  and  $\text{CeO}_2\text{-WO}_3/\text{MCM-22}$  (Fig. S13). The catalyst was treated in a  $\text{NO}+\text{O}_2$

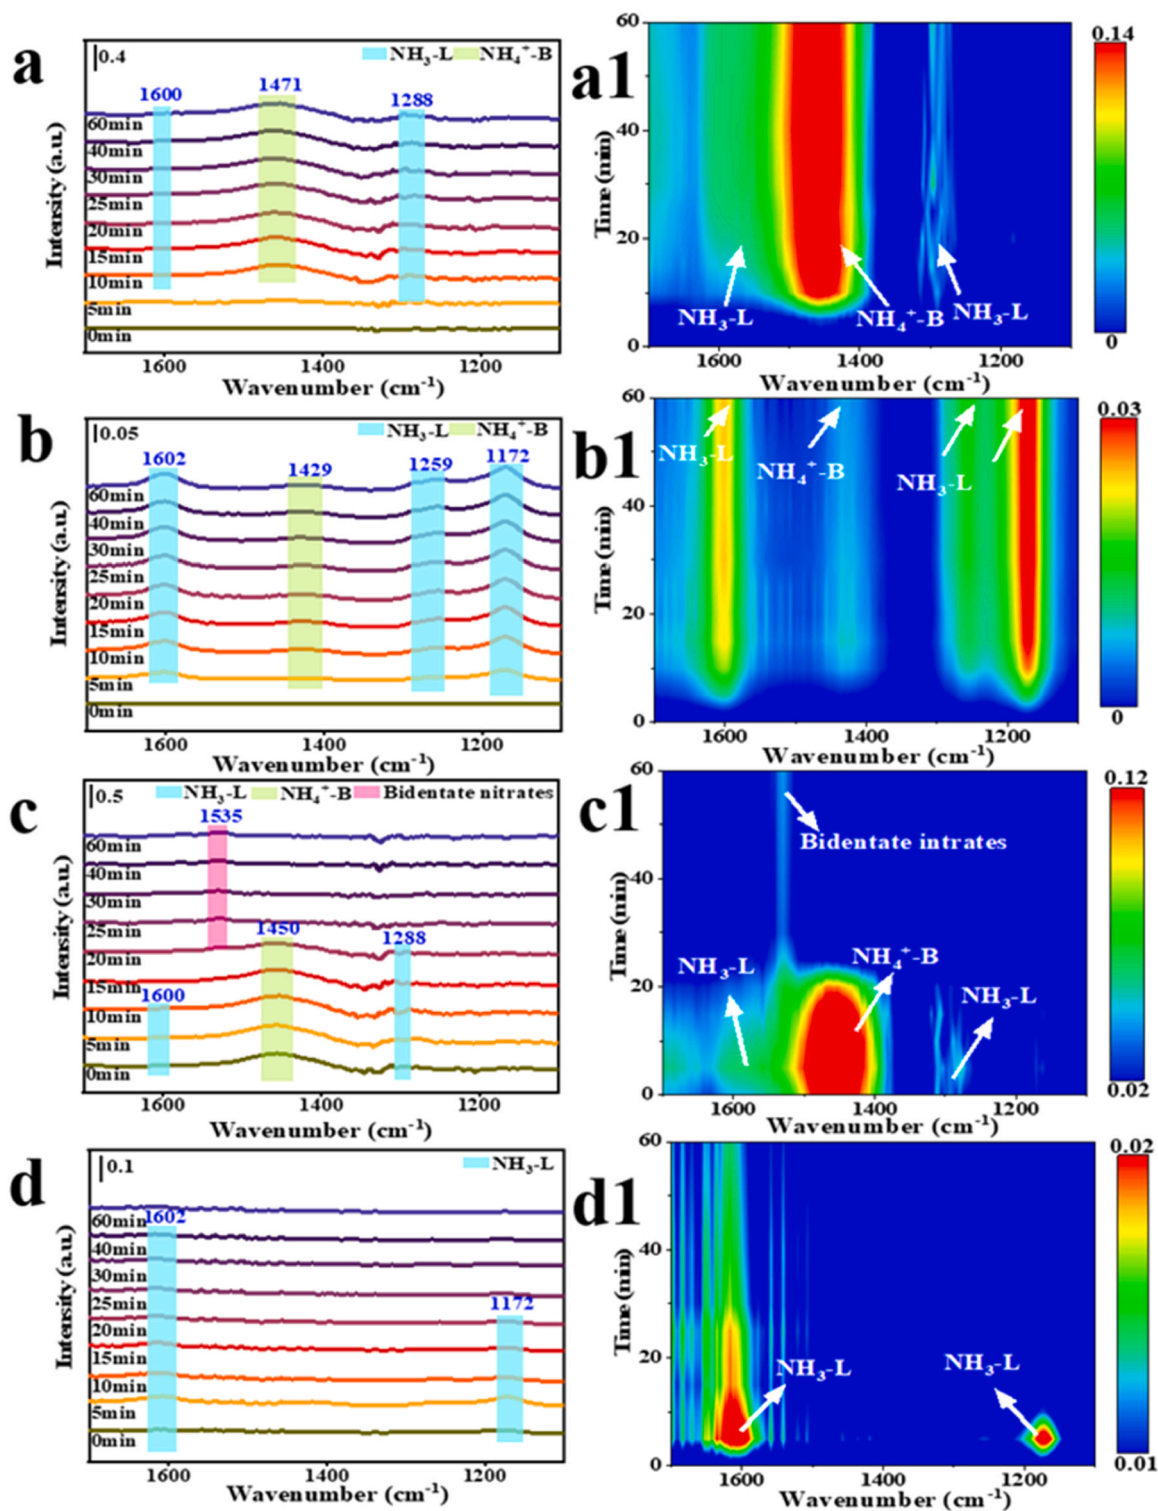

Fig. 4. The transient  $\text{NH}_3$  adsorption DRIFTS profiles and the corresponding mapping results over (a, a<sub>1</sub>)  $\text{CeO}_2\text{-WO}_3/\text{MCM-22-K}$  and (b, b<sub>1</sub>)  $\text{CeO}_2\text{-WO}_3\text{-K}$ ; In situ DRIFTS of the transient reactions between  $\text{NO}+\text{O}_2$  and pre-adsorbed  $\text{NH}_3$  over (c, c<sub>1</sub>)  $\text{CeO}_2\text{-WO}_3/\text{MCM-22-K}$  and (d, d<sub>1</sub>)  $\text{CeO}_2\text{-WO}_3\text{-K}$  measured at  $200^\circ\text{C}$ .

atmosphere for 1 h, purged with pure  $N_2$  for 30 min to remove the physically absorbed  $NO_x$  species, and finally exposed to an  $NH_3$  atmosphere for 1 h. The peaks attributable to bidentate nitrate ( $1579\text{ cm}^{-1}$ ) were exhibited in  $CeO_2-WO_3/MCM-22$ . After exposure to  $NH_3$ , peaks attributable to B acid sites and L acid sites were observed and the peaks assigned to the bidentate were covered. It was observed that no significant difference occurred when reaction gases were fed into the catalyst in reverse order, indicating a weak or no reaction between nitrate species and  $NH_3$  species.  $NH_3$  adsorbed on the catalyst reacted directly with  $NO + O_2$ , and the catalytic reaction followed E-R mechanism. The  $CeO_2-WO_3$ , the nitrate ( $1232\text{ cm}^{-1}$ ) and adsorbed  $NO_2$  species ( $1604\text{ cm}^{-1}$ ) were observed on the catalyst by purging  $NO + O_2$  [42]. After exposure to  $NH_3$ , the peak attributable to adsorbed  $NO_2$  species significantly decreased within 10 min, and then peaks attributable to B acid sites ( $1666$  and  $1421\text{ cm}^{-1}$ ) and L acid sites ( $1591$  and  $1180\text{ cm}^{-1}$ ) were exhibited. It can be inferred that  $CeO_2-WO_3$  followed L-H mechanism.

The introduction of K reduced the acidity of  $CeO_2-WO_3$  and  $CeO_2-WO_3/MCM-22$ . *In situ* DRIFTS analysis was conducted to evaluate the effect of K on the adsorption behavior of substances on the catalysts, and the  $CeO_2-WO_3-K$  and  $CeO_2-WO_3/MCM-22-K$  were characterized (Fig. 4). After K poisoning, the position of  $CeO_2-WO_3/MCM-22-K$  signal peaks exhibited no significant variation, indicating that there were still abundant acid sites on the catalyst for  $NH_3$  adsorption (Fig. 4a). It was plausible that the acid sites of MCM-22 tended to combine with the foreign alkali poisons K as sacrificial sites, thus the active Ce-W component was retained. However, the  $CeO_2-WO_3-K$ , the faint peaks belonging to L ( $1602$ ,  $1259$  and  $1172\text{ cm}^{-1}$ ) and B ( $1429\text{ cm}^{-1}$ ) acid sites were observed after  $NH_3$  adsorption [43], indicating that K significantly reduced the acid sites especially the B acid sites on  $CeO_2-WO_3-K$ . In a previous study [18],  $NH_3$  adsorption occurred at the B acid sites formed by the  $W=O$  bond on cerium tungstate, indicating that K inhibited the adsorption of  $NH_3$  by occupying the B acid site of  $CeO_2-WO_3$ , thus hindering the  $NH_3$ -SCR reaction and leading to the conspicuous deactivation of the catalyst. The *in situ* DRIFTS results of  $NO+O_2$  reaction with pre-adsorbed  $NH_3$  over  $CeO_2-WO_3-K$  and  $CeO_2-WO_3/MCM-22-K$  at  $200^\circ\text{C}$  (Fig. 4c, d). The peaks attributable to B ( $1471\text{ cm}^{-1}$ ) and L ( $1288\text{ cm}^{-1}$ ) acid sites were detected on the  $CeO_2-WO_3/MCM-22-K$  catalyst. After passing  $NO+O_2$ , both B and L acid sites vanished within 30 min. Simultaneously, the peak attributable to bidentate nitrate ( $1535\text{ cm}^{-1}$ ) was observed (Fig. 4c). Conversely, the weak peaks attributable to L acid sites ( $1602$  and  $1172\text{ cm}^{-1}$ ) were observed on  $CeO_2-WO_3-K$  (Fig. 4d). After the introduction of  $NO+O_2$ , the L acid sites was reduced slightly, indicating that K severely inhibited  $NH_3$ -SCR reaction on  $CeO_2-WO_3$ .

The *in situ* DRIFTS results of  $NH_3$  reaction with pre-adsorbed  $NO+O_2$  over  $CeO_2-WO_3-K$  and  $CeO_2-WO_3/MCM-22-K$  were observed (Fig. S15). The peak attributable to bidentate nitrate ( $1535\text{ cm}^{-1}$ ) appeared on  $CeO_2-WO_3/MCM-22-K$ . After exposure to  $NH_3$ , the peaks attributable to B acid sites ( $1473\text{ cm}^{-1}$ ) and L acid sites ( $1600$  and  $1288\text{ cm}^{-1}$ ) were observed within 10 min and the peak attributable to bidentate nitrate were covered (Fig. S15a). It was observed that no significant difference occurred on  $CeO_2-WO_3/MCM-22$  after K was introduced. The slight signal peaks of L acid sites ( $1602$ ,  $1259$  and  $1172\text{ cm}^{-1}$ ) were detected on  $CeO_2-WO_3-K$  after  $NH_3$  adsorption (Fig. S15b). In previous study [18], gaseous  $NH_3$  did not react directly with  $NO$  on  $CeO_2-WO_3$ , indicating that the main reason for the deactivation of  $CeO_2-WO_3$  was that K occupied the B acid sites of  $W=O$  species on cerium tungstate. Thus, inhibiting the adsorption of  $NH_3$  species, and seriously hindering the E-R reaction path. However, for  $CeO_2-WO_3/MCM-22-K$ , the K preferentially combined with the acid sites of the MCM-22 molecular sieve, thereby, releasing the occupied B acid site on cerium tungstate and restoring the E-R reaction path. Fig. 5 illustrates the proposed reaction pathways of  $CeO_2-WO_3-K$  and  $CeO_2-WO_3/MCM-22-K$ . The deactivation effect of K on the  $CeO_2-WO_3$  catalyst primarily resulted in a decrease of B acid sites on cerium tungstate, inhibiting  $NH_3$  adsorption and

Fig. 5. Schematic illustration of the anti-K poisoning mechanism on  $CeO_2-WO_3$  and  $CeO_2-WO_3/MCM-22$  catalysts.

hindering the E-R pathway. In contrast, the acid sites of the MCM-22 molecular sieve on the  $CeO_2-WO_3/MCM-22-K$  preferentially combined with K as sacrificial sites, protecting the active  $CeO_2-WO_3$  component and restoring the E-R reaction path. Therefore,  $CeO_2-WO_3/MCM-22$  catalyst exhibited conspicuous K tolerance. In this study, the finding provides a theoretical foundation for the development of an environmentally friendly  $NH_3$ -SCR catalyst with exceptional K resistance.

#### 4. Conclusions

In summary, compared with  $CeO_2-WO_3$  catalyst,  $CeO_2-WO_3/MCM-22$  catalyst exhibited minimal activity loss after 1 wt% K poisoning and maintained good activity after 2 wt% K poisoning. The incorporation of layered molecular sieve MCM-22 resulted in an increased number of strong acid sites in the  $CeO_2-WO_3/MCM-22$  catalyst, which facilitated high-temperature  $NH_3$ -SCR reaction. In the case of  $CeO_2-WO_3$  catalyst, K occupied the B acid sites formed by  $W=O$  species on the cerium tungstate and decreased the redox performance of the  $CeO_2-WO_3$  catalyst. Thus, inhibiting the adsorption of  $NH_3$  species and limiting the redox cycle ( $NH_3$  activation), which combination led to the slow reaction rate and severe deactivation of the  $CeO_2-WO_3$  catalyst. However, the  $CeO_2-WO_3/MCM-22$  catalyst, due to the acid-base coordination theory, the acid sites of zeolite MCM-22 preferentially combined with foreign K poisons, which acted as sacrificial sites to protect the occupied B acid sites on the cerium tungstate and restore the acid site cycle for  $NH_3$  adsorption. Moreover, the reduction performance and the ratio of  $Ce^{3+}$  and  $O_a$  were well maintained in the  $CeO_2-WO_3/MCM-22$  catalyst after K poisoning. Generally, the  $CeO_2-WO_3/MCM-22$  catalyst exhibited excellent denitrification activity and prominent K resistance.
